Title : Exe26 - Clusters of Grain

Name: Chuay Xiang Ze

IC Number: 021224070255

Date : 1/8/2023

Introduction : Learning how to cluster in real datasets

Conclusion : Managed to complete tasks relating to the topic.

How many clusters of grain?

This exercise is taken and modified from https://github.com/benjaminwilson/python-clustering-exercises (https://github.com/benjaminwilson/python-clustering-exercises)

This is a class to choose a good number of clusters for a dataset using the k-means inertia graph. You are given a dataset of the measurements of samples of grain. What's a good number of clusters in this case?

This dataset was obtained from the UCI (https://archive.ics.uci.edu/ml/datasets/seeds).

Step 1: Load the dataset *(written for you)*.

In [2]:

```
import pandas as pd

seeds_df = pd.read_csv('./seeds.csv')
# forget about the grain variety for the moment - we'll use this later
del seeds_df['grain_variety']
```

Step 2: Display the DataFrame to inspect the data. Notice that there are 7 columns - so each grain sample (row) is a point in 7D space! Scatter plots can't help us here.

In [3]:

```
seeds_df
```

Out[3]:

	area	perimeter	compactness	length	width	asymmetry_coefficient	groove_length
0	15.26	14.84	0.8710	5.763	3.312	2.221	5.220
1	14.88	14.57	0.8811	5.554	3.333	1.018	4.956
2	14.29	14.09	0.9050	5.291	3.337	2.699	4.825
3	13.84	13.94	0.8955	5.324	3.379	2.259	4.805
4	16.14	14.99	0.9034	5.658	3.562	1.355	5.175
...	...	...	...	...	...	...	...
205	12.19	13.20	0.8783	5.137	2.981	3.631	4.870
206	11.23	12.88	0.8511	5.140	2.795	4.325	5.003
207	13.20	13.66	0.8883	5.236	3.232	8.315	5.056
208	11.84	13.21	0.8521	5.175	2.836	3.598	5.044
209	12.30	13.34	0.8684	5.243	2.974	5.637	5.063

210 rows × 7 columns

Step 3: Extract the measurements from the DataFrame using its `.values` attribute:

In [4]:

```
measurements = seeds_df.values
```

Step 4: *(Written for you)*. Measure the quality of clusterings with different numbers of clusters using the inertia. For each of the given values of `k`, perform the following steps:

- Create a `KMeans` instance called `model` with `k` clusters.
- Fit the model to the grain data `samples`.
- Append the value of the `inertia_` attribute of `model` to the list `inertias`.

In [5]:

```
from sklearn.cluster import KMeans

# Define a list to store the inertia values for different numbers of clusters
inertias = []

# Define the range of clusters you want to test (e.g., from 1 to 10 clusters)
num_clusters_range = range(1, 6)

# Loop through the range of clusters and compute the inertia for each k
for k in num_clusters_range:
    # Create a KMeans instance with k clusters
    model = KMeans(n_clusters=k, random_state=0)

    # Fit the model to the grain data samples
    model.fit(measurements)

    # Append the inertia value to the list 'inertias'
    inertias.append(model.inertia_)

import matplotlib.pyplot as plt

# Plot the inertia values against the number of clusters
plt.plot(num_clusters_range, inertias, marker='o')
plt.xlabel('Number of Clusters (k)')
plt.ylabel('Inertia')
plt.title('Inertia vs. Number of Clusters')
plt.grid(True)
plt.show()
```

```

re better!

```
model.inertia_
```

Out[23]:

```
201.39807107056689
```

Excellent work! You can see from the graph the "best" number of clusters. Use this value for the next steps.

Step 6: Create a `KMeans` model called `model` with the best value from the above steps.

In [6]:

```
model = KMeans(n_clusters = 3)
```

Step 7: Use the .fit_predict() method of model to fit it to samples and derive the cluster labels.

Calling .fit_predict() is the same as calling .fit() and then calling .predict().

In [10]:

```
labels = model.fit_predict(measurements)
labels
```

```
C:\Anaconda\envs\python-dscourse\lib\site-packages\sklearn\cluster\_kmean

```

Out[10]:

```
array([2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 0, 2, 2, 0, 2, 2,
       2, 2, 2, 2, 0, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 1, 2, 0, 2, 2, 2, 2,
       2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 0, 0, 0, 0, 2, 2,
       2, 2, 2, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
       1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1,
       1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 1, 1, 1, 1, 1, 1, 1,
       2, 2, 2, 2, 1, 2, 2, 2, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
       0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
       0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
       0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0])
```

Step 8: Create a DataFrame `df` with two columns named `'labels'` and `'varieties'`, using `labels` and `varieties`, respectively, for the column values.

In [11]:

```
new_df = pd.read_csv('./seeds.csv')
varieties = new_df['grain_variety']

df = pd.DataFrame({'labels': labels, 'varieties': varieties})
df
```

Out[11]:

	labels	varieties
0	2	Kama wheat
1	2	Kama wheat
2	2	Kama wheat
3	2	Kama wheat
4	2	Kama wheat
...	...	...
205	0	Canadian wheat
206	0	Canadian wheat
207	0	Canadian wheat
208	0	Canadian wheat
209	0	Canadian wheat

210 rows × 2 columns

Step 9: Use the `pd.crosstab()` function on `df['labels']` and `df['varieties']` to count the number of times each grain variety coincides with each cluster label. Assign the result to `ct` .

In [16]:

```
ct = pd.crosstab(df['labels'], df['varieties'])
```

Step 10: Display `ct` by evaluating it - and inspect your cross-tabulation! You'll see that your clustering is pretty good.

In [15]:

```
ct
```

Out[15]:

varieties labels	Canadian wheat	Kama wheat	Rosa wheat
0	68	9	0
1	0	1	60
2	2	60	10

Now you are done. If you wish, you can also try to plot the clusters to visualize it.

In [23]:

```
kmeans = KMeans(n_clusters=best_k, init='k-means++', max_iter=300, n_init=10, random_sta

y_kmeans = kmeans.fit_predict(measurements)

plt.scatter(measurements[:, 0], measurements[:, 1], c=y_kmeans, s=50, cmap='viridis', la
plt.scatter(kmeans.cluster_centers_[:, 0], kmeans.cluster_centers_[:, 1], c='blue', s=20

plt.xlabel('Feature 1')
plt.ylabel('Feature 2')
plt.title(f'K-Means Clustering with {best_k} Clusters')

plt.legend()
plt.show()
```

```
C:\Anaconda\envs\python-dscourse\lib\site-packages\sklearn\cluster\_kmean
s.py:1436: UserWarning: KMeans is known to have a memory leak on Windows w
ith MKL, when there are less chunks than available threads. You can avoid
it by setting the environment variable OMP_NUM_THREADS=1.
  warnings.warn(
```
